The Steps for analyzing Algorithm:

- time
- space
- network transformation
- power consumption
- cpu registers

Common Data Structure Operations

Data Structure	Time Complexity								Space Complexity
	Average				Worst				Worst
	Access	Search	Insertion	Deletion	Access	Search	Insertion	Deletion	
Array	$O(1)$	$O(n)$	$O(n)$	$O(n)$	$O(1)$	$O(n)$	$O(n)$	$O(n)$	$O(n)$
Stack	$O(n)$	$O(n)$	$O(1)$	$O(1)$	$O(n)$	$O(n)$	$O(1)$	$O(1)$	$O(n)$
Queue	$O(n)$	$O(n)$	$O(1)$	$O(1)$	$O(n)$	$O(n)$	$O(1)$	$O(1)$	$O(n)$
Singly-Linked List	$O(n)$	$O(n)$	$O(1)$	$O(1)$	$O(n)$	$O(n)$	$O(1)$	$O(1)$	$O(n)$
Doubly-Linked List	$O(n)$	$O(n)$	$O(1)$	$O(1)$	$O(n)$	$O(n)$	$O(1)$	$O(1)$	$O(n)$

Recursion :

Recursion is the process of defining a problem (or the solution to a problem) in terms of (a simpler version) itself.

Law of Recursive:

- A recursive algorithm must have a base case (when to stop)

- A recursive algorithm must move toward the base case
- A recursive algorithm must call itself recursively

Code:

Example 1:

```
def count_down(n):
    print(n,end=' ')
    if n>0:
        count_down(n-1)
```

Example 2:

```
def sum_list(list):
    if len(list)==0:
        return 0
    return list[0]+sum_list(list[1:])
```

Example 3:

Convert decimal to different base

```
def tostr(n,base):
    digits='0123456789ABCDEF'
    if n<base:
        return digits[n]
    return tostr(n // base,base) + digits[n % base]
```

Example 4:

Check Palindrome

- Recursive:

```
def pallidnrome_recursive(num):
    s=str(num)
    if len(s) < 1:
        return True
    else:
        if s[0] == s[-1]:
            return pallidnrome_recursive(s[1:-1])
        else:
            return False
```

- Second Way:

```
def reverseDigits(num) :

    rev_num = 0;
    while (num > 0) :
        rev_num = rev_num * 10 + num % 10
        num = num // 10

    return rev_num
```

Function to check if n is Palindrome

```
def isPalindrome(n) :

    # get the reverse of n
    rev_n = reverseDigits(n);
```

```
# Check if rev_n and n are same or not.
if (rev_n == n) :
    return 1
else :
    return 0
```

Example 5:

Fibonacci sequence:

- Recursive:

```
def fib_recursive(num):
    if num <=1:
        return num
    return fib(num-1)+fib(num-2)
```

- Loop:

```
def fib_loop(num):
    n1,n2=0,1
    count=0
    if num==0:
        return 0
    elif num==1:
        return 1
    else:
        while count < num:
            nth=n1+n2
            n1=n2 # swap
            n2=nth # swap
            count +=1
        return n1
```

Example 6(Check if the item in the node list):

```
def search(item,node):
    if node.item==item:
        return True
    elif node==None:
        return False
    else:
        return search(item,node.rest)
```

Stack(LIFO):

Stack Array:

Stack class implemented with array

```
class Stack:
    """Implements an efficient last-in first-out Abstract Data Type using a Python List"""

    # capacity is max number of Nodes, init_items is optional List parameter for initialization
    # if the length of the init_items List exceeds capacity, raise IndexError
    def __init__(self, capacity, init_items=None):
        """Creates an empty stack with a capacity"""
        self.capacity = capacity # capacity of stack
        self.items = [None]*capacity # array for stack
```

            else:
                break
    return com
```

The $\theta(n)$ steps. Each steps have $\theta(n)$ swaps.

Selection Sort:

Figure 7: Selection Sort:

- Find the minimum value in the list
- Swap it with the value in the first position
- Repeat the steps above for the remainder of the list (starting at the second position and advancing each time)

Code:

```
def selection_sort(A):
    # Traverse through all array elements
    for i in range(len(A)):

        # Find the minimum element in remaining
        # unsorted array
        min_idx = i
        for j in range(i+1, len(A)):
            if A[min_idx] > A[j]:
                min_idx = j

        # Swap the found minimum element with
        # the first element
        A[i], A[min_idx] = A[min_idx], A[i]
    return A
```

Merge Sort:

Code:

```
def mergeSort(myList):
    if len(myList) > 1:
        mid = len(myList) // 2
        left = myList[:mid]
        right = myList[mid:]
```

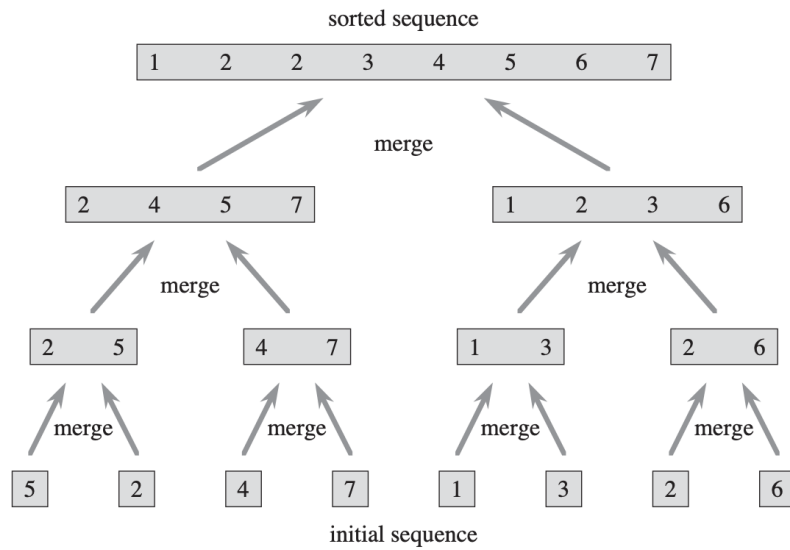

Figure 8: Merge Sort

```

# Recursive call on each half
mergeSort(left)
mergeSort(right)

# Two iterators for traversing the two halves
i = 0
j = 0

# Iterator for the main list
k = 0

while i < len(left) and j < len(right):
    if left[i] < right[j]:
        # The value from the left half has been used
        myList[k] = left[i]
        # Move the iterator forward
        i += 1
    else:
        myList[k] = right[j]
        j += 1
    # Move to the next slot
    k += 1

# For all the remaining values
while i < len(left):
    myList[k] = left[i]
    i += 1
    k += 1

while j < len(right):
    myList[k] = right[j]
    j += 1
    k += 1

```

```
myList = [54,26,93,17,77,31,44,55,20]
mergeSort(myList)
print(myList)
```

The complexity $\theta(n)$.

$$T(n) = c_1 + 2T\left(\frac{n}{2}\right) + c.n$$

Quick Sort:

The time complexity in best way is $O(n \log(n))$ and the worst case scenario is when is whole list already sorted so the time complexity is $O(n^2)$.

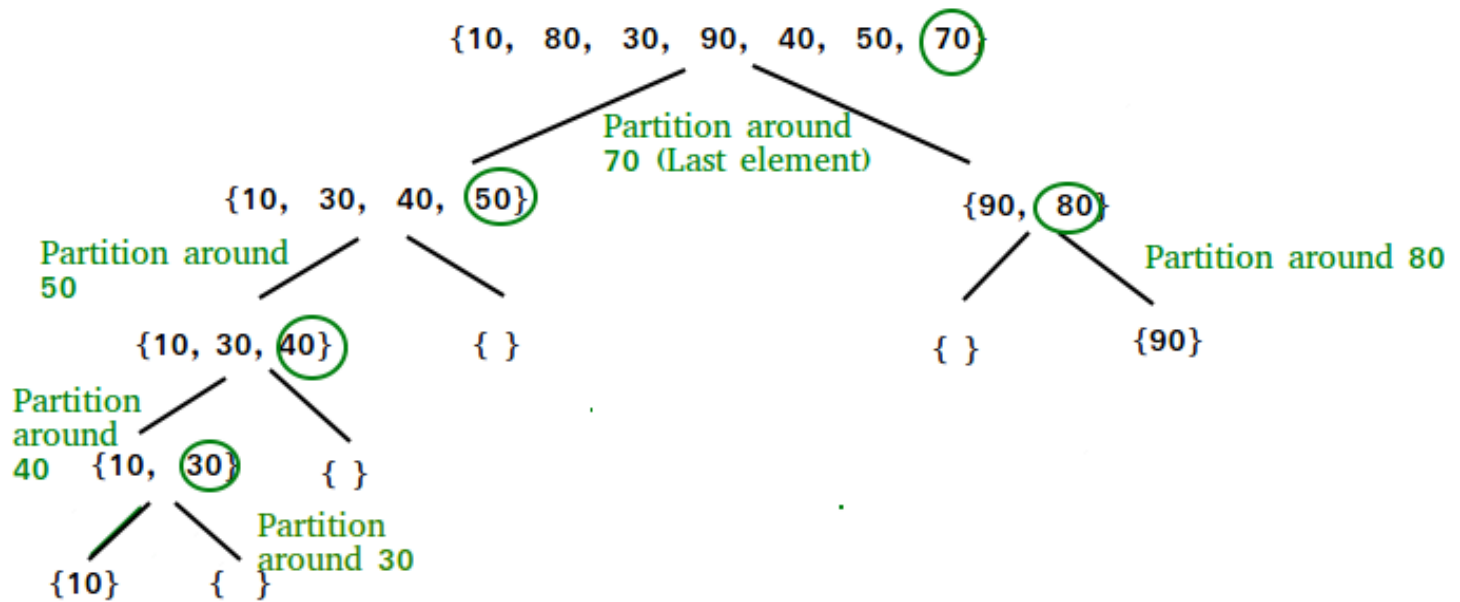

Figure 9: Quick Sort

Code:

```
def partition(arr,low,high):
    i = ( low-1 )           # index of smaller element
    pivot = arr[high]       # pivot

    for j in range(low , high):

        # If current element is smaller than or
        # equal to pivot
        if arr[j] <= pivot:

            # increment index of smaller element
            i = i+1
            arr[i],arr[j] = arr[j],arr[i]

    arr[i+1],arr[high] = arr[high],arr[i+1]
    return ( i+1 )

# The main function that implements QuickSort
# arr[] --> Array to be sorted,
```

```
# low --> Starting index,
# high --> Ending index

# Function to do Quick sort
def quickSort(arr,low,high):
    if low < high:

        # pi is partitioning index, arr[p] is now
        # at right place
        pi = partition(arr,low,high)

        # Separately sort elements before
        # partition and after partition
        quickSort(arr, low, pi-1)
        quickSort(arr, pi+1, high)
```

Heap Sort:

[Reference Book](#)

Figure 10: Type of Heap

BigO: Heap enqueue, dequeue, perc_up, perc_down are $O(\log(n))$, build heap is $O(n)$.

- its left child is at $**2*i**$.
- its right child is at $**2*i+1**$.
- its parent is at $\lfloor \frac{i}{2} \rfloor$.

Max Heap: it is a complete binary and all node have greater than descending.

Min Heap: it is a complete binary and all node have less than descending.

Code:

```
class MaxHeap:

    def __init__(self, capacity=50):

Graph:

Figure 11: Graph

Breath First Search:

Sudo Code:

- While Q is not empty:
- dequeue the vertex, add to output
- queue adjacent vertices that have not been visited

Depth First search:

Sudo Code:

- While stack not empty:
- pop the vertex
- if not visited
 - Mark as visited
 - add to the output
- push the adjacent vertices < HEAD

Top Logical Sorting:

- while stack not empty:
- pop the output of vertex
- reduce the indegree of all adjacent vertex
- push all new vertex with indegree of zero

```
from sys import argv
from stack_array import *
```

```
def tsort(vertices):
    """
    * Performs a topological sort of the specified directed acyclic graph. The
    * graph is given as a list of vertices where each pair of vertices represents
    * an edge in the graph. The resulting string return value will be formatted
    * identically to the Unix utility {code tsort}. That is, one vertex per
    * line in topologically sorted order.
    """
```

```

* Raises a ValueError if:
*   - vertices is empty with the message "input contains no edges"           Done
*   - vertices has an odd number of vertices (incomplete pair) with the      Done
*     message "input contains an odd number of tokens"
*   - the graph contains a cycle (isn't acyclic) with the message
*     "input contains a cycle"'''

Red Black Tree:

Time complexity:

height: $O(\log(n))$

	Worst Case	Average Case
Space	$O(n)$	$O(n)$
Search	$O(\log_2 n)$	$O(\log_2 n)$
Insert	$O(\log_2 n)$	$O(\log_2 n)$
Delete	$O(\log_2 n)$	$O(\log_2 n)$

Figure 12: BigO Red Black Tree

Recognizing:

- **Root Property:** The root is Black
- **External Property:** Every external node is Black
- **Red property:** The children of a red node are Black
- **Depth property:** All external nodes have the same black Depth.

Insertion:

Case1:

- Relabel the nodes to a, b and c from left to right.
- Replace the original z with b. Make a and c its children. Keep inorder relationships unchanged.

Case2:

- Color y and s to black and z to red
- If z is the root or the parent of z is red, repeat recoloring for z.
