[Lecture Video for the Book](#)

Recursion :

Recursion is the process of defining a problem (or the solution to a problem) in terms of (a simpler version) itself.

Law of Recursive:

- A recursive algorithm must have a base case (when to stop)
- A recursive algorithm must move toward the base case
- A recursive algorithm must call itself recursively

Code:

Example 1:

```python
def count_down(n):
    print(n,end='')
    if n>0:
        count_down(n-1)
```

Example 2:

```python
def sum_list(list):
    if len(list)==0:
        return 0
    return list[0]+sum_list(list[1:])
```

Example 3:

Convert decimal to different base

```python
def tostr(n,base):
    digits='0123456789ABCDEF'
    if n<base:
        return digits[n]
    return tostr(n // base,base) + digits[n % base]
```

Example 4:

Check Palindrome

- Recursive:

```python
def pallidnrome_recursive(num):
    s=str(num)
    if len(s) < 1:
```

```python
            return True
        else:
            if s[0] == s[-1]:
                return pallidnrome_recursive(s[1:-1])
            else:
                return False
```

- Second Way:

```python
def reverseDigits(num) :

    rev_num = 0;
    while (num > 0) :
        rev_num = rev_num * 10 + num % 10
        num = num // 10

    return rev_num

# Function to check if n is Palindrome
def isPalindrome(n) :

    # get the reverse of n
    rev_n = reverseDigits(n);

    # Check if rev_n and n are same or not.
    if (rev_n == n) :
        return 1
    else :
        return 0
```

Example 5:

Fibonacci sequence:

- Recursive:

```python
def fib_recursive(num):
    if num <=1:
        return num
    return fib(num-1)+fib(num-2)
```

- Loop:

```python
def fib_loop(num):
    n1,n2=0,1
    count=0
    if num==0:
        return 0
    elif num==1:
        return 1
    else:
        while count <num:
            nth=n1+n2
            n1=n2   # swap
            n2=nth # swap
            count +=1
        return n1
```

Stack:

Stack Array:

```python
# Stack class implemented with array
class Stack:
    """Implements an efficient last-in first-out Abstract Data Type using a Python List"""

    # capacity is max number of Nodes, init_items is optional List parameter for initialization
    # if the length of the init_items List exceeds capacity, raise IndexError
    def __init__(self, capacity, init_items=None):
        """Creates an empty stack with a capacity"""
        self.capacity = capacity          # capacity of stack
        self.items = [None]*capacity      # array for stack

```

Insertion Sort

Code:

```python
def insertion_sort(A):
    for j in range(2,len(A)):
        key=A[j]
        i=j-1
        while i>0 and A[i]>key:
            A[i+1]=A[i]
            i=i-1
        A[i+1]=key
```
Figure 1: Insertion Sort

```
        return A
```

The $\theta(n)$ steps. Each steps have $\theta(n)$ swaps.

## Merge Sort:

Figure 2: Merge Sort

Code:

```python
def mergeSort(myList):
    if len(myList) > 1:
        mid = len(myList) // 2
        left = myList[:mid]
        right = myList[mid:]

        # Recursive call on each half
        mergeSort(left)
        mergeSort(right)

        # Two iterators for traversing the two halves
        i = 0
        j = 0

        # Iterator for the main list
        k = 0

        while i < len(left) and j < len(right):
            if left[i] < right[j]:
                # The value from the left half has been used
                myList[k] = left[i]
```

```
            # Move the iterator forward
            i += 1
        else:
            myList[k] = right[j]
            j += 1
        # Move to the next slot
        k += 1

    # For all the remaining values
    while i < len(left):
        myList[k] = left[i]
        i += 1
        k += 1

    while j < len(right):
        myList[k]=right[j]
        j += 1
        k += 1

myList = [54,26,93,17,77,31,44,55,20]
mergeSort(myList)
print(myList)
```

The complexity $\theta(n)$.

$$T(n) = c_1 + 2T(\tfrac{n}{2}) + c.n$$

Selection Sort:

Code:

```
def selection_sort(A):
    # Traverse through all array elements
    for i in range(len(A)):

        # Find the minimum element in remaining
        # unsorted array
        min_idx = i
        for j in range(i+1, len(A)):
            if A[min_idx] > A[j]:
                min_idx = j

        # Swap the found minimum element with
        # the first element
        A[i], A[min_idx] = A[min_idx], A[i]
    return A
```
